MSAI-631-B01: Artificial Intelligence for Huma-Computer Interactions

Dr. Alan Dennis

December 07, 2025

Abstract

Artificial intelligence (AI) has transformed the expectations users have for digital systems, particularly regarding personalization and dynamic interaction. Adaptive User Interfaces (AUIs) and Intelligent User Interfaces (IUIs) represent a shift from static design toward systems that evolve based on user behavior, accessibility needs, and contextual factors.

This report presents a hypothetical adaptive UI solution called Adaptive Health Navigator, a conceptual healthcare-focused interface that personalizes the user's experience during runtime using AI techniques.

The report outlines the theoretical foundations of AUIs and AI-based adaptive human–computer interaction (HCI), details the conceptual design process, documents challenges encountered, and discusses the broader implications of adaptive interfaces in real-world applications.

This project demonstrates how AI can meaningfully enhance usability, accessibility, and engagement across modern interactive systems.

Introduction

Human-computer interaction has historically emphasized structured design methods, task analysis, and usability evaluation methodologies. However, modern digital systems now go beyond fixed design to incorporate continuous adaptation driven by AI, user modeling, and interaction analytics.

According to Kore (2022), AI-driven experiences create more intuitive and supportive interfaces by tailoring system behavior to each individual's cognitive preferences, habits, and environmental conditions.

This project centers on designing a hypothetical AI-based adaptive user interface named Adaptive Health Navigator, envisioned as a patient-facing application that adjusts its interface dynamically based on real-time interaction patterns.

Instead of implementing a working prototype, the emphasis is on detailing the conceptual architecture, adaptation strategies, and design processes that align with the assignment guidelines. The report also evaluates how AI contributes to HCI evolution, defining adaptive UIs, intelligent UIs, and AI-based adaptive HCI in the context of contemporary research.

Defining Adaptive User Interfaces

Adaptive User Interfaces (AUIs) are interfaces that systematically adjust their structure, presentation, or behavior based on user characteristics or context. Miraz et al. (2021) describe AUIs as “plastic” systems capable of modifying themselves without requiring manual customization.

Core Characteristics of AUIs

Personalization: Learns user preferences to tailor layout, navigation, and visual design.

Context-awareness: Adjusts based on device type, lighting conditions, or user environment.

Behavioral adaptation: Changes interaction pathways when users struggle or perform repetitive tasks.

Accessibility-focused adaptation: Enhances readability, contrast, or complexity based on user ability.

Examples include reading apps that enlarge text automatically, flight apps that simplify workflows for frequent travelers, and smartwatch interfaces that adapt based on activity level.

AUIs are not inherently intelligent; some rely entirely on rule-based triggers. Their strength lies in enabling each user to receive a tailored experience.

Intelligent User Interfaces and Their Relationship to AUIs

Intelligent User Interfaces (IUIs) incorporate AI-based reasoning, enabling systems to understand user intent, anticipate needs, and make decisions without explicit rules. IUIs frequently rely on:

Machine learning

Predictive analytics

Natural language processing (NLP)

Knowledge-based reasoning

User modeling

Mack et al. (2021) emphasize that IUIs expand beyond simple adaptation to include meaningful intelligence, such as interpreting accessibility needs, predicting emotional states, and optimizing workflows autonomously.

Relationship Between AUIs and IUIs

AUIs adapt the interface;

IUIs understand the user and make predictive decisions.

Thus, AUIs can operate without intelligence, but IUIs almost always include adaptive behavior.

The hypothetical system described in this report combines both concepts.

AI-Based Adaptive Human–Computer Interaction

AI-based adaptive HCI is the integration of artificial intelligence into interactive systems to enable interfaces to learn, reason, and adapt continuously throughout their use. Kore (2022) notes that AI increases system sensitivity to user patterns, enabling deeper personalization.

AI Techniques Commonly Used in Adaptive HCI

Supervised learning to predict user preferences

Reinforcement learning to optimize UI changes

NLP to support conversational interactions

Clustering to group users by behavioral similarity

Context-aware computing to adjust based on environment

These methods collectively enable systems that are proactive, constantly learning, and capable of modifying behavior autonomously.

Hypothetical Project: Adaptive Health Navigator

To fulfill the assignment requirements using a non-coded solution, this project conceptualizes Adaptive Health Navigator, a hypothetical healthcare application that adjusts its interface based on usage behaviors, accessibility patterns, and predicted emotional states.

Use Case Scenario

Adaptive Health Navigator is intended for patients managing chronic conditions.

Different users have different needs:

A senior user may require high-contrast text and simplified navigation.

A diabetic patient may frequently monitor glucose data, requiring quick access.

A user experiencing stress may benefit from fewer visual stimuli.

By applying AI-based adaptive principles, the application evolves to support each user individually.

System Architecture Overview

Although conceptual, the system is structured around industry-standard adaptive UI principles:

1. Interaction Monitoring Layer

Records user actions such as:

Navigation patterns

Tapping speed

Task completion time

Error frequency

Preferred settings

2. AI Personalization Engine

Analyzes incoming data using:

Decision trees for UI adjustments

Lightweight predictive models for preference estimation

Contextual triggers (e.g., time of day, device orientation)

3. Adaptive Interface Renderer

Chooses UI variants for:

Layout and component placement

Color theme

Text size

Feature prioritization

Workflow complexity

4. Accessibility Adaptation Module

Powered by guidelines from Microsoft Inclusive Design (n.d.) to respond to:

Visual impairments

Motor-control difficulties

Cognitive load indicators

Adaptive Behaviors Designed for the System

The Adaptive Health Navigator includes multiple adaptation capabilities:

Behavioral Adaptation

If the user takes too long to locate a feature → system highlights key elements.

If errors increase → workflows simplify automatically.

Contextual Adaptation

Low-light mode activates at night.

If device battery is low → background data usage is minimized.

Personalized Navigation

Frequently accessed features move to the top of the dashboard.

Irrelevant or unused modules collapse into secondary menus.

Accessibility-Driven Adaptation

Text enlarges when a user zooms multiple times.

If motion gestures are difficult → gesture-based inputs are replaced with large buttons.

Design and Development Steps

The assignment required documenting the process used to construct the adaptive system.

Even though the system is hypothetical, its development process follows standard HCI project methodology:

Step 1: Concept Selection

Healthcare was chosen due to:

High need for accessibility

Regular repetitive interactions

Importance of reducing cognitive load

Step 2: User Modeling

Personas created:

Older adult with low vision

Chronic illness patient

Tech-savvy user seeking analytics

User with motor impairments

Step 3: Identifying Adaptation Opportunities

Analyzed how each persona interacts with a health system and identified adaptation triggers.

Step 4: Designing Adaptive Logic

Mapped user interaction data to interface adjustments.

Step 5: Integrating AI Techniques

AI models selected for:

Preference prediction

Behavioral clustering

Accessibility inference

Step 6: Designing UI Variants

Created multiple versions of dashboards, text sizes, layouts, and workflows.

Step 7: Testing Scenarios

Ran thought experiments and mapped how the interface should respond across different user journeys.

Challenges Encountered

1. Understanding the Boundaries of Adaptation

The main challenge was determining how frequently the system should adapt without frustrating the user. Excessive adaptation can cause inconsistency and confusion.

2. Balancing Automation and User Control

Users want personalization but also need predictable and stable UI layouts.

3. Accessibility Considerations

Accessibility adaptation must be precise to avoid making incorrect assumptions about user ability.

4. Ethical and Privacy Challenges

Inspired by Goldfarb and Que (2023), the system must avoid collecting unnecessary personal data and ensure transparent handling of health information.

Benefits of Adaptive UIs

Through research, several clear benefits emerged:

Improved accessibility for individuals with diverse abilities (Interaction Design Foundation, n.d.).

Reduced cognitive load for users performing frequent tasks.

Increased engagement through personalization.

Higher task success rate by reducing errors.

Better user satisfaction, as the system feels “intelligent” and responsive.

These benefits justify the relevance of adaptive UIs in healthcare, finance, transportation, and education.

Conclusion

This project explored the conceptual design of an AI-driven adaptive user interface - the Adaptive Health Navigator. Through an analysis of adaptive UIs, intelligent UIs, and AI-based adaptive HCI, this report demonstrates the value of runtime personalization in modern software systems.

While the system was hypothetical, the design process aligns closely with real-world adaptive HCI methods used by organizations developing inclusive and responsive technologies. Adaptive interfaces supported by AI are essential for future digital ecosystems, enabling systems to learn from users and support them more effectively.

The source files for the conceptual system are hosted in a GitHub repository created specifically for this project (GitHub, 2025)

Disclosure of AI Tools

ChatGPT and Grammarly were used to assist in generating ideas, drafting, reorganizing sections, and refining grammar. No code was generated for this hypothetical system.
